How to detect a Label change (workarounds)

1. Use `onChanged()` instead (recommended)

`onChanged()` is called when *any* property changes — including `Label`.

```
python

class MyFeature:
    def onChanged(self, fp, prop):
        if prop == "Label":
            print("Label changed to:", fp.Label)
```

⚠ Important notes:

- `onChanged()` may be called **a lot**
- Do **not** do heavy geometry work here
- Do **not** modify properties that trigger recursion

Best use: bookkeeping, renaming linked objects, syncing UI state.

2. Force a recompute manually (not ideal)

If you really want `execute()` to run after a label change:

```
python

obj.Label = "NewLabel"
obj.touch()
obj.Document.recompute()
```

This is **explicit**, not automatic, and generally discouraged for label-only changes.
